git

- <https://git-scm.com/>
- initially designed and developed to manage source code for the Linux operating system in 2005
- git is a program, or in more contemporary terms an app
- it manages directories of files - these are called repositories or repos

git

- so changes to a repo are recorded as commits
- commits contain data and metadata, like author, date+time, relation to other commits
- commits always happen on a branch
- the default branch is called 'master' - it is just a name

branches

merge branches

collaboration?

- share repos with each other
- not through email or dropbox :)
- set up a remote on a server
- collaborators sync their copies with the remote one, agree on authoritative changes when conflicts occur

remotes

- a popular option: <https://github.com>
- another option: <https://about.gitlab.com/>
- there are many more

the commit

- each commit also has a commit message
- describe what you have done - important project metadata
- a good commit message introduces the reader to the nature of the changes that were applied
- normally it has a short heading and an extended description if relevant
- all commit messages are collected in a commit log

github

1. signup
2. create a repo
3. create a file, add changes, commit it
4. add more changes, commit it
5. view the difference, comment on them
6. read the commit log
